Received 18 August, 2013; Accepted 22 July, 2014

The aim of this study was to investigate the oral acute toxicity effects of dichloromethane fraction of ethanol extract of stem bark of *Piliostigma reticulatum* on rats using conventional methods. The rats were divided in nine groups. The control group received normal saline. The others groups received the order of doses of 800, 1000, 2000, 3000, 4000, 5000, 6000 and 7000 mg/kg body weight. However, the rats showed signs of immobility with the dichloromethane fraction at doses of 5000 mg/kg body weight and mortality at doses of 2000 mg/kg body weight. The LD50 was 3000 mg/kg body weight and the quotient LD5/LD95 was 0.17. This value shows that the toxic dose and the therapeutic dose were not distant. Phytochemical screening revealed the presence of tannins, flavonoids, polyphenols and reducing sugars in the stem bark of *P. reticulatum*. These results suggest that dichloromethane fraction of the ethanol extract of stem bark of *P. reticulatum* could be used with some degree of safety especially by oral route.

**Key words:** Acute, toxicity, stem, bark, *Piliostigma reticulatum*, rats.

INTRODUCTION

Hundreds of years ago, plants were known to play mainly nutritional roles. Today they play an additional important function in treatment of diverse pathologies. Plants, although pharmacologically active, are used without knowledge of toxicological parameters. For this reason, the World Health Organisation approved the use of herbal products for national policies and drug regulatory measures in order to strengthen research and evaluation of the toxicity of these products (Saxena, 2001). Thus, the toxicity of certain plants has been shown in many studies. For example, the acute toxicity of *Anogeissus leiocarpus, Daphnia magna* and *Cansjera rheedii* has

been studied respectively by Agaie et al. (2007), Altindag et al. (2008) and Moumniassamy et al. (2010).

Pilostigma reticulatum which is the object of our study is traditionally used in Côte d’Ivoire for diarrhoea including bacterial diarrhoea (Yelemou et al., 2007; Dosso et al., 2012). Thus Babajide et al. (2008) have shown that the pilostigmol (6-C-methyl-2-p-hydroxyphenylxychromonol), a substance isolated in P. reticulatum, inhibited Escherichia coli with a MIC equal to 2.57 μg/mL. In our previous study, results showed that an ethanol extract of the stem bark of P. reticulatum significantly reduced the gastrointestinal transit, the number, volume and weight of faeces of rats (Dosso et al., 2012). Also, the extract was not toxic in rats. In the present study, the aim of the current investigation was to determine the toxic effects of the dichloromethane fraction of a crude ethanol extract of the stem bark of P. reticulatum on rats as well as to screen its phytochemical constituents.

MATERIALS AND METHODS

Plant collection

Stem barks of P. reticulatum (DC.) Horscht (Ceasalpiniaceae) were collected in Abidjan (South region of Côte d’Ivoire) in October 2007. The plant was identified and authenticated by Pr AKE-ASSI Laurent. A voucher specimen (No. 18033) of the plant has been deposited in the herbarium of the National Centre of Floristic of University of Cocody-Abidjan.

Preparation of dichloromethane fraction

Stem barks of P. reticulatum were washed with distilled water, cleaned, cut into smaller pieces and kept at room temperature for two weeks. Then they were ground into a fine powder. The powder (100 g) was extracted with two liters of a solution of ethanol (96%) / water (80:20) for 24 h under constant stirring (this operation was repeated twice).

The extract was filtered twice through cotton wool, then through Whatman filter paper (No 1). The filtrate was evaporated to dryness using a rotavapor (Buchi R110/NKE6540/2) at 45°C, and dried under reduced pressure. Percentage yield was found to be 13.6%.

After successive liquid-liquid fractionations, five fractions (heptane, dichloromethane, ethyle acetate, butanol and water) were obtained from the crude ethanol extract (Harborn, 1984; Samsam-Shariat, 1992).

Acute toxicity studies

Fifty forth albino rats were divided into nine groups of six rats each and were given graded doses (800, 1000, 2000, 3000, 4000, 5000, 6000 and 7000 mg/kg body weight) of the fraction by oral route. The rats were observed for signs of toxicity and death over a period of 72 h as described by Lorke (1983). The first group received single oral dose of 2 ml of normal saline through the same route. The LD50, LD50 and LD95 of the fraction were calculated using the arithmetic method of Karber as modified by Aliu and Nwude (1982).

Phytochemical analysis of the fraction

The dichloromethane fraction was screened for the presence of tannins, polyphenols and flavonoids. Reducing sugars were present, and anthraquiones, alkaloids, coumarins, polyterpenes and sterols were absent.

RESULTS

Phytochemical analysis of the fraction

Phytochemical screening tests of dichloromethane fraction for various constituents revealed the presence of major components such as tannins, polyphenols and flavonoids. Reducing sugars were present, and anthraquinones, alkaloids, coumarins, polyterpenes and sterols were absent.

Acute toxicity studies

The results in the Table 1 show that with the dichloromethane fraction at doses of 800 to 4000 mg/kg body weight, the survival animals are mobile. At the dose of 5000 mg/kg body weight, we observed the immobility of rats. Also the animals began to die at dose of 2000 mg/kg body weight. At dose of 1000 mg/kg body weight, we had 0% of mortality. The LD50 (50% of mortality) is 3000 mg/kg body weight. Also, at the dose of 7000 mg/kg body weight, 100% of animals did not survive with dichloromethane fraction (Tables 1 and 2). The DL5 and DL95 are respectively 1118 and 6425 mg/kg body weight (Figure 1). The quotient DL5 / DL95 reports 0.17. This result is far from 1.

DISCUSSION

The study of the acute toxicity of dichloromethane fraction showed that the LD50 is equal to 3000 mg/mL body weight. Animals showed toxicity signs in a dose-dependent manner. Also, at a dose of 7000 mg/mL, there were no survivors. The results obtained with the dichloromethane fraction, are consistent with those of Diallo and

Figure 1. Evolution of mortality percentage in rats treated with dichloromethane fraction.
Diouf (2002) which showed that the LD50 of the aqueous extract of Piliostigma reticulatum leaves in rats was 1700 mg/mL body weight. The leaves of this plant therefore center more toxic substances in the leaves than stem bark. The LD50 obtained with our active fraction is higher than that obtained with the aqueous extract of the leaves. Agaie et al. (2007) studied the acute toxicity of aqueous extract of leaves of Anogeissus leiocarpus rats and was near 1200 mg/kg body weight like LD50. This plant is more toxic than that used in our studies with a low LD50. The study of the toxicological properties of the latex of Calotropis procera yielded approximately a LD50 like 2611.75 mg/kg body weight (Lohoues et al., 2006). The latex of Calotropis procera focuses more toxic substances than the dichloromethane fraction.

The quotient DL5 / LD50 (0.17) is far from 1. These results indicate that the use of this fraction is not safe in its therapeutic use with the understanding that the therapeutic dose is not distinct from its toxic dose (Tamboura et al., 2005). These results are contrary to those obtained by Lohoues et al. (2006). According to these authors, the DL5 / DL95 quotient in the study of the acute toxicity of the latex of C. procera was 0.71 - 1. The therapeutic dose of this product is distinct from the toxic dose. The latex of this plant is probably non toxic.

After administration of the fraction of plant, immobility and death of animals are observed at high doses. These clinical manifestations had been also reported by Lohoues et al. (2006) in the study of the acute toxicity of the latex of C. procera in Côte d’Ivoire.

The phytochemical screening of dichloromethane fraction showed the presence of flavonoids, tannins, polyphenols and reducing sugars. Our tests have not revealed the presence of alkaloids, quinones, coumarins, saponins, sterols and polyterpenes. Phytochemical studies by Kubmarawa et al. (2007) on the aqueous extract of the roots of P. reticulatum showed the presence of chemical compounds such as saponins, tannins and flavonoids. Contrastingly, chemical compounds in the same plant could be explained by the different organs used in the studies or the difference of natural environments. Thus, we observed a variation of secondary metabolites in the same plant according the living environment (Sofowora, 1996).

The active compounds observed in the stem bark of P. reticulatum could explain the toxicity signs in rats. Thus, when in excess in the body, certain chemical compounds may exceed their therapeutic activities, incite some malfunctions or lethal disorders (Lohoues et al., 2006). For example, astringent tannins have a role in reducing foods functions or lethal disorders (Lohoues et al., 2006). For this reason, it will be necessary to eliminate the probable toxic substances in the dichloromethane fraction like tannins, flavonoids, reducing sugars and polyphenols.

It will be necessary to eliminate the probable toxic substances in dichloromethane fraction. Thus, the fraction could be used to treat diarrhea without risk. Also, the use of aerial parts of the plant could represent an alternative to the utilization of its roots, therefore limiting the biodiversity degradation.

Conflict of Interests

The author(s) have not declared any conflict of interests.

ACKNOWLEDGEMENTS

This project was supported in part by the Non-Governmental Organisation for the Promotion of Scientific Research in African Traditional Medicine (NGO "PRORESMAT"). The authors wish to thank Professor Ake-Assi Laurent of the National Centre of Floristic, University of Cocody-Abidjan for botanical identification of the plant, Doctor AMOATENG Patrick of Department of Pharmacology and Toxicology, University of Accra (Ghana), for arranging the graph.
